Abstract

The importance of cybersecurity has increased in recent years and more and more organizations have to invest in cybersecurity. The problem organizations face is in determining how large an investment they need to make. A number of studies have tried to address this by using cybersecurity risk analysis and using it to help determine the amount of investment. In this research we propose a model for cybersecurity investment based on the business impact of cyberattacks. Our model focuses on the mechanism of cyberattacks and identifies the critical factors that have a significant impact on the organization’s business. To improve the accuracy of the prediction, we continue to research the previous studies and gather more case studies to enhance and validate this model.

The overview of the model and estimation results

In our research we start by analyzing and evaluating the business impact of cyberattacks. To analyze the impact, we examine the current cybersecurity risk analysis literature, and postulate a sequence of cyberattack events and their effect on businesses as shown in Figure 1. Cyberattacks are identified as security incidents, security incidents have a business impact, and the business impact result in financial losses. Next, we examine what type of factors affect this sequence of events. Based on the general characteristics of each phase, three assumptions can be derived from figure 1, (a) lower cybersecurity preparedness has a higher likelihood of a significant security incident. (b) higher the dependence of an organization on information technology, bigger is the business interruption. (c) larger the organization size, more significant is the business interruption. Then, we identified the factors in Table 1 which can quantitatively represent the assumed relationship in the model. By using these factors, we propose a mathematical model which estimates the possible negative business impact of business interruption.

Model: Business Impact of business interruption = k ⋅ R ⋅ T ⋅ D ⋅ CS

Table.2 provides an example of fitting a real case to the model. Figure 2 shows the comparison of the estimation results and real data from annual reports of organizations.

We plan to enhance and validate this model using additional data and case studies.
