## **Abstract**

The recent increase of mobile device adoption in the workplace as part of knowledge-sharing activities has caused a rise of knowledge leakage risk (KLR). KLR is a significant problem for knowledge-intensive organizations operating in highly-competitive environments. Accordingly, organizations have an increasing need to manage risk strategies in order to mitigate KLR. The contribution of this study is to provide a theoretical conceptual model to (1) identify the determinants that influence KLR through the use of mobile devices and (2) present how such factors inform organizational KLR mitigation strategies to safeguard against leakage incidents. We take a context-specific approach by drawing on literature in the area of mobile-device-usage-context, particularly “social context interaction framework” and “model of context in computer science”, organizing the constructs under human, organizational and technological perspectives to understand the contexts within which knowledge leakage occurs and finally, propose a conceptual model that can aid organizations in developing KLR strategies.

**Keywords:** Knowledge management, knowledge leakage, knowledge leakage risk, mobile context, mobile device.

## 1 Introduction

Due to the growing adoption of boundary-spanning information technologies in the workplace, such as mobile devices, knowledge-intensive organizations operating in highly-competitive environments are presented with the challenge of preventing increasing leakage of sensitive details such as intellectual property, trade secrets and business strategies (Ahmad et al. 2014; Mohamed et al. 2007; Parker 2012).

Recently, a key focus of literature related to mobility, is how organizations struggle with leakage of sensitive organizational information across various avenues, such as social media, cloud computing and portable data devices (Ahmad et al. 2014, 2015; Jiang et al. 2013; Krishnamurthy and Wills 2010; Mohamed et al. 2006). Although much of the literature has focused on technical aspects of leakage (i.e., data and information), scant research has been conducted on knowledge leakage through mobile devices in particular (Agudelo et al. 2015; Ghosh and Rai 2013; Zahadat et al. 2015).

While the use of mobile devices (owned either by the organization or the employee) has shown to be convenient, the convenience of using such devices by knowledge workers in knowledge-sharing activities poses a problem for confidentiality. Challenges in confidentiality occur as a result of employee's security (mis)behaviours in addition to technological (e.g., firewall, antivirus, and compartmentalization) and formal (i.e., policies, standards and procedures) controls (Agudelo et al. 2015; Ahmad et al. 2014).

In knowledge-intensive organizations, where knowledge is the main source of innovation and competitive advantage, addressing knowledge leakage risk (KLR) becomes paramount as knowledge is considered a critical asset for sustained competitive advantage (Grant 1996). In order to sustain such advantage in highly competitive environments, organizations must continuously develop capabilities and strategies that leverage and manage such knowledge assets (Alavi and Leidner 2001a; Bosua and Scheepers 2007; Teece 2007).

However, despite its relevance to organizations, knowledge leakage has not been addressed in much of the knowledge management literature, as the focus has been traditionally on fostering knowledge sharing and creation of workflows within organizations (Bosua and Scheepers 2007; Frishammar et al. 2015; Manhart and Thalmann 2015; Moein et al. 2015). Furthermore, failing to address knowledge leakage presents a significant risk, since it can cause the replication of ideas by external organizations hindering the exploitation of innovation (Manhart and Thalmann 2015; Shedden et al. 2011).

This paper addresses the gap found in the literature regarding KLR through mobile devices in knowledge-intensive organizations operating in highly-competitive environment by providing a conceptual model that assists with determining the factors that cause such risk. We therefore pose the following question:

1. *How does the knowledge leakage risk through mobile devices inform organizations' mitigation strategies?*

To answer this question, this paper takes a contextual approach to understand how risk changes depending on the circumstances within which knowledge leakage occurs.

A research conceptual model is proposed to explain the factors that influence the risk of knowledge leakage through the use of mobile devices. Understanding the determinants behind KLR can assist organizations in developing more effective formal (policy), informal (culture, behavior, Security Education Training and Awareness) and technological controls that can address this issue (Dhillon 2007).

This paper is structured as follows: First, it provides salient concepts found in the key background literature. Second, a conceptual model is proposed followed by a brief discussion of the main constructs. Finally, the study outlines potential contributions and future work.

## 2 Key Background Literature

In this section, relevant areas of literature are presented and discussed. First, we discuss the definition of knowledge and knowledge leakage from the knowledge management literature. Second, we summarize the relevant concepts of mobility and contexts associated with mobile devices to define the main constructs used in the proposed research conceptual model that follows.

### 2.1 Knowledge

There is abundant literature addressing the difference between data, information and knowledge in sources such as Boisot and Canals (2004) and Dahlbom and Mathiassen (1993). Boisot and Canals (2004) state that raw data becomes information when individuals are able to add meaning from such data, and, adding the contextual understanding in conjunction with the background of such data allows knowledge to be inferred. Therefore, knowledge is intertwined with data and information. Consequently, the leakage of knowledge is also related to the leakage of data and information. This distinction is important for our study because from the leakage of data/information, leakage of knowledge may occur just by drawing on inference, that is, we gain knowledge by inference – the process of inferring things based on what is already known (Dahlbom and Mathiassen 1993).

This study adopts the definition of knowledge given by Davenport and Prusak (1998):

*“Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms.”*

According to this definition, knowledge is complex, a mixture of various elements, intuitive and therefore, hard to capture. Moreover, knowledge is embedded in people, and as such, may be unpredictable and intangible. Knowledge derives from information and to turn information into knowledge, human mediation is required (Davenport and Prusak 1998). Although knowledge is further divided into tacit (present in employee’s minds) and explicit (knowledge that has been codified into artefacts) (Nonaka 1991), from the perspective of mobile devices, this study will only focus on explicit knowledge leakage, since its disclosure is more likely to occur in mobile device settings than tacit knowledge leakage, such as when key personnel leave the organization to a competitor (Frishammar et al. 2015).

Information and knowledge have become key strategic assets (Bollinger and Smith 2001) for knowledge-intensive organizations to achieve sustained competitive advantage, innovation and value creation (Nonaka and Toyama 2003; Sveiby 1997). Similarly, MacDougall and Hurst (2005) contend that the adoption of knowledge workers, employees who produce value by utilizing their knowledge rather than physical labor, allows organizations to develop their knowledge assets. These individuals perform work based on their information assets for the coordination and management of organizational activities (Sorensen et al. 2008). Ristovska et al. (2012) also focus on the importance of knowledge embedded in knowledge workers as it is an organizational asset for achieving sustainable competitive advantage which can be materialized into documentation and organizational processes. The importance of expertise in organizations relies heavily on exercising specialist knowledge and competencies, or alternatively, the management of organizational competencies and capabilities which belong to employees or knowledge workers (Blackler 1995; Thompson and Walsham 2004).

Knowledge, in this sense is the information residing in the mind of the knowledge worker, personalized by the individual based on facts, procedures, concepts, interpretations, ideas, observations and judgments which is codified into artefacts such as documentation, processes and guidelines (Alavi and Leidner 2001b).

## 2.2 Knowledge Leakage

Knowledge leakage (KL) is defined in this paper: as the **accidental** or **deliberate** loss or unauthorized transfer of organizational knowledge intended to stay within a firm’s boundary resulting in the deterioration of competitiveness and industrial position of the organization (Frishammar et al. 2015; Nunes et al. 2006).

According to the knowledge leakage definition, KL can occur from the disclosure of sensitive details, information or data as meaning can be inferred by a competitor based on understanding of context and leveraged even further to generate insights and advance their own competitiveness to the detriment of the organization’s competitive advantage (Ahmad et al. 2015; Annansingh 2012; Davenport and Prusak 1998; Molok et al. 2010).

Although knowledge loss due to a lack of knowledge management procedures is also defined as knowledge leakage (Nunes et al. 2006), the focus in this study will be on knowledge leakage directly or indirectly caused by knowledge workers when performing knowledge work through mobile devices, particularly, the accidental loss derived from misbehaviours (failing to comply policy and procedures), as it is considered the most challenging channel of leakage for organizations to control (Nunes et al. 2006). The inadvertent loss, caused by insiders can be influenced by addressing human behaviour habits through policy, culture and awareness as opposed to malicious insiders who are deliberately seeking to leak knowledge/information (Colwill 2009) and are not influenced by such controls. Therefore, the focus on this study will be on addressing unintentional leakage caused by non-malicious insiders.

Drawing upon the standard definition of risk, knowledge leakage risk (KLR) is defined as the probability that KL occurs multiplied by the impact of the KL to the organization (Ahmad et al. 2015), i.e.,  $KLR = Probability\ of\ KL \times Impact\ of\ KL\ to\ the\ Organization$ .

## 2.3 Mobility

The risk of knowledge leakage is significantly elevated as the adoption of mobile devices increases within organizations. Changes in the technology environment have propelled transformation of how employees perform knowledge work, thus, influencing and facilitating the way users behave and create knowledge. As Green (2002) claims, the change in the technology environment is enabled through the development of the modern metropolis embedded with strong telecommunication infrastructures. An increase of strength and reliability of Wi-Fi and cellular networks, as well as the increased availability of unsecured public Wi-Fi hotspots, allows users to stay connected in many different environments and situations between the home and workplace. The shift from hard-disk storage to cloud storage is a significant example of change in technology infrastructure as well as the adoption and appropriation of boundary-spanning technologies (Ahmad et al. 2014). These infrastructure changes enable technologies such as mobile devices to move and operate seamlessly through networks for both work and personal use (Sorensen et al. 2008).

Globalization and economies of scale have stimulated the phenomenon of consumerization which describes the wider adoption of technologies such as mobile devices due to lower costs of production and distribution (Agudelo et al. 2015; Moschella et al. 2004). Mobile devices provide users with technological capabilities to perform work

outside the physical workplace through access to corporate assets such as emails, enabling higher productivity which has driven the adoption of BYOD (Bring Your Own Device) policies within organizations (Agudelo et al. 2015; Ghosh and Rai 2013; Miller et al. 2012; Sarker and Wells 2003; Zahadat et al. 2015). Further, supported by changes in technological infrastructure, mobile devices are becoming highly capable and personally located devices near users which are always on and are connected to a variety of networks extending the corporate environment (Chigona et al. 2012).

Currently, some generic leakage prevention controls related to the usage of mobile devices include, mainly, technical controls such as MDM - Mobile Device Management, compartmentalization of sensitive content through containerization, network controls, cryptography and classification of information (Zahadat et al. 2015); legal controls for knowledge protection such as Non-Disclosure agreements, contracts and patents; and organizational controls such as policies, procedures and guidelines (Ahmad et al. 2014). However, the literature concerning controls targeting human (mis)behaviours is rather scant.

## 2.4 Contexts

In order to address the issue of knowledge leakage risk through mobile devices in organizations, this paper takes a context-specific perspective to understand how risk changes according to the circumstances and factors within which leakage occurs.

Although knowledge leakage is enabled by the employee in control of the mobile device, there are multiple environmental factors that affect the use of mobile devices for knowledge work. Nonaka and Toyama (2003) suggest that knowledge creation, sharing and distribution are achieved through the interactions between the individual, the organization and the environment. The environment influences the individual while, at the same time, individuals are continuously recreating their environment through their social interactions. This proposes that social factors in human interactions constantly change the environment in which knowledge is created. Nonaka and Toyama (2003) developed a model of knowledge creation in order to explain the conversion of knowledge through interactions between individuals, groups of individuals, organizations and the environment. This model not only highlights the importance of the environmental and organizational circumstances around an individual, it also highlights the importance of the social environment where individuals interact within groups to obtain information (Nonaka and Konno 1998; Nonaka and Toyama 2003).

These environments are referred to in the literature, from a mobile device perspective, as the “context” of the mobile device usage (Abdoul Aziz Diallo 2012; Chen and Nath 2008; Schilit et al. 1994). Table 1 summarises the mobile-usage-context taxonomy found in the literature. Understanding the different contexts of mobile device usage in these different settings (technological, environmental, organizational, social and personal) is important to assess the overall security risk of the device as the potential enabler of or medium through which knowledge leakage can occur in conjunction with the user and the environment within which the device is used. The importance of mobile device contexts stems from the fact that without the context within which knowledge leakage occurs, it is not possible to determine the level of risk (Benítez-Guerrero et al. 2012; Bradley and Dunlop 2005).

Mohamed et al. (2006) found that one of the key routes of knowledge leakage is *people* through social contexts of mobile usage. These routes include training courses, collaborations with universities, multi-disciplinary teams and temporary workers. Through social interactions in these different contexts, knowledge is shared or accessible to other users. Social context also includes the use of social networking platforms on mobile devices (Krishnamurthy and Wills 2010).

Due to the nature of mobile device usage, the context of a device usage transitions across many changes in technical, social and locational environments (technological, environmental, organizational and personal contexts). Through the interactions of these dynamic contexts with one another, the risk of knowledge leakage also becomes dynamic. Thus, knowledge can be leaked through the technological, organizational, personal, and network context amongst others (Diallo et al. 2011, 2014). As an illustration of this phenomenon, Astani et al (2013) found that a significant amount of employees from information sensitive industries such as banking, connected their mobile devices to unsecured public Wi-Fi networks (i.e., technological context, environmental context) which exposes the device to the security vulnerabilities of those networks and may be used as a vehicle for knowledge leakage. By simply changing the network connection to a public Wi-Fi network, these employees are drastically changing the technological and environmental contexts and, therefore, their “mobile device usage context” in which the device is operating, changing the risk profile of their device, drastically affecting the potential for knowledge leakage.

Context	Reference	Description
Environmental	Kofod-Petersen & Cassens (2006); Nieto, Botía, & Gómez-Skarmeta, (2006)	The environmental context is defined as the conjunction of the following contexts: temporal context, spatial context, social context, technological context, and business context
Personal	Kofod-Petersen &	The personal context provides the attributes of cognitive skills and draws

	Cassens (2006)	on psychological and physiological contexts: psychological, goal, cognition, physiological, identity, actions
Social	Nieto et al., (2006)	Provides a social perspective of context, which captures the attributes of people (e.g. attitude, skills, and values) and the relationship of these people among each other and within the organization and collective structures.
Spatial	Kofod-Petersen & Cassens (2006)	Provides attributes of location and answers the question of where the interaction is conducted. The following are some constructs of this category: spatial objects, localization, location, season, weather, geography, routes, building
Temporal	Abdoul Aziz Diallo (2012)	Temporal context is defined in terms of when the activity is performed: absolute date (year, month, day, hour, minutes, seconds), relative date (yesterday, tomorrow, next month, next year, etc.)
User	Abdoul Aziz Diallo (2012)	User context extends on personal context adding the technological dimension and the mobile device from HCI (Human-Computer interaction) perspective
Location	Abdoul Aziz Diallo (2012)	Location context is part of the spatial context and it is defined by: places, GPS location
Business	Abdoul Aziz Diallo (2012)	The business context supports the decision making process by assisting in the decision maker's situation awareness cognitive process, and taking in to consideration the following aspects: indicators, objectives, partners, competitors, market
Technological	Abdoul Aziz Diallo (2012)	Provides the technological and technical attributes such as: network connections, infrastructure, equipment, devices and systems. It is an aggregate context which consists of other technical constituents such as spatial, user and location context.
Organizational	(Crossler et al. 2013; Furnell and Rajendran 2012; Whitman, Michael and Mattord 2011)	Defines the social interactions within the workplace and security behaviour determined by Information Security Policies, Security Education Training and Awareness, Culture, Standards, organizational processes and procedures
Device	(Diallo et al. 2014; Kofod-Petersen and Cassens 2006; Nieto et al. 2006)	Technological features such as device identifier and device type (i.e., laptop, tablet, smartphone)

*Table 1. Taxonomy of Mobile Usage Contexts derived from the literature*

These contexts are relevant to the usage of the mobile device. If a user changes devices (device context, technological context), for example, then his/her overall context (user context) will change. The new device may not have the same functions as the previous one, resulting in a new number of contexts affecting the device. Since the old device is no longer used by the user, various contexts (e.g., social, user, and location contexts) no longer apply to it. This highlights the dynamic changes in knowledge leakage risks as the circumstances of how the knowledge worker uses their mobile device change.

Additionally, people and objects are constantly moving in and out of different context risks and the relevancy of these objects and people to the context are dynamic and hence the security threat of knowledge leaking is constantly changing. For example, if John is sitting in a coffee store reading his corporate emails from his tablet before heading into work (environmental, personal and technological context) and a new customer sits down behind John (social context), John's risk context has changed as the customer may potentially read John's tablet screen (shoulder surfing). John then receives a phone call (personal and social context), which introduces a new person (caller) into the context, with whom he then discusses the agenda of the morning meeting (organizational context). This change in context risk now involves the surrounding people within earshot drastically increasing the potential for knowledge leakage.

From the literature there have been many approaches to modelling the contextual information surrounding mobiles across many disciplines of Information Technology. Most of the research into the *contextual information* and *context* of mobile devices has been focused on the technical and computing issues (Benítez-Guerrero et al. 2012; Bradley and Dunlop 2005; Diallo et al. 2013; Hofer et al. 2003; Kofod-Petersen and Cassens 2006; Schilit et al. 1994).

Similarly, Hofer et al. (2003) also extended and modelled these dimensions of context into device context (e.g. device identifier and device type) and network context (e.g. network connection types) which were included as the

technical context, in a more recent study, by Abdoul Aziz Diallo (2012). However, these studies failed to address the social context, neglecting the human perspective from the mobile contextual model, namely, user behaviour.

On the other hand, Chen & Nath (2008) asserted that the social context is not independent of the technical context; it is the “interaction and compatibility” between the two that determine the effectiveness of a work system. This interdependency of the social and technical context is further reflected by Bradley and Dunlop’s, (2005) “Model of Context in Computer Science” which aims to illustrate the key components and characteristics of context which are present during user-computer interaction. The key idea derived from Chen and Nath’s model of context is that there are multiple contexts that contribute to the mobile usage context of mobile devices.

Expanding on Chen & Nath’s (2008) social context interaction framework and Bradley and Dunlop’s (2005) model of context, we address the gap in the literature by modelling such contexts from the human perspective and defining a high-level construct, *knowledge leakage risk* through mobile devices, as a formative construct (i.e., comprised of mobile usage contexts) which in turn informs risk mitigation strategies in organizations. This conceptual model is further explained in the following section.

### 3 The Research Model

Figure 1 depicts our proposed research conceptual model. We develop our research model by identifying key constructs based on the two models mentioned in the previous section: Chen and Nath’s (2008) “social context interaction framework” and Bradley and Dunlop’s (2005) “model of context in computer science”.

The criteria to select contexts for the conceptual model were based on the social context interaction framework (Chen and Nath 2008): 1) Personal context; 2) Social context are grouped together under Human factors which refer to motivations and cognitive processes, as well as social norms that are explicit and implicit from human behaviours and social interaction; 3) Environmental context; 4) Organizational context which constitute the Enterprise factors and refer to the organizational culture and behaviour, operating environment (regulations) not only within the workplace but also outside (macro environment). Finally, the Technical factors are composed of 5) Device context; 6) Technological context and refer to the technology and information systems that enable and facilitate the adoption of technology and technical artefacts to perform knowledge-sharing activities.

The constructs have been clustered in three groups: human, organizational and technical factors as defined in the “Integrative Model of IT Business Value” based on the resource-based view of the firm (Melville et al. 2004) as this model provides a framework to understand how internal (organizational resources) and external (trading partners, competitive and macro environment) factors impact organizational performance, which in our case, relates to how the mobile device usage contexts through the formative construct (i.e., KLR) contributes to improvement of organizational information and knowledge security performance signified in the construct organizational KLR mitigation strategies. In Table 2 the propositions are listed and explained with references to the literature.

Figure 1. Proposed Research Conceptual Model. Adapted from Bradley & Dunlop (2005), Chen & Nath (2008) and Melville et al. (2004)

Construct	Definition	Reference
Organizational KLR	Formal, informal and technical risk control strategies, used by organizations to safeguard knowledge assets at risk. Such strategies aim to reduce risk impact or	(ISO/IEC 27005:2011 2011;

Mitigation Strategies	probability (risk reduction), as well as share, avoid, transfer or accept any residual risk remaining after the risk treatment.	Dhillon 2007)
Knowledge leakage Risk through Mobile Devices	Knowledge leakage risk caused by the use of mobile devices in organizations. This high-level construct will be operationalized used a qualitative scale, i.e., low, medium and high.	(27005:2011 2011; Agudelo et al. 2015; Ahmad et al. 2015)
Human Factors	The combination of personal and social contexts referring to individual's self-efficacy, personality traits, competences, behaviour, attitude, cognitive capabilities, motivations, experiences (personal context) as well as group's competences, social norms, peer's influence and superior's influence (social context).	(Ajzen 1991; Bandura 1978; Bradley and Dunlop 2005; Chen and Nath 2008; Melville et al. 2004)
Enterprise Factors	The combination of environmental and organizational contexts referring to external conditions (e.g., competitors, industry, external locations) as well as internal organizational resources and capabilities (e.g., policies, culture, processes, routines).	(Ajzen 1991; Bradley and Dunlop 2005; Chen and Nath 2008; Melville et al. 2004)
Technical Factors	The combination of device and technological contexts referring to the infrastructure and technological resources internal and external to the organization that enable and support knowledge-sharing activities.	(Ajzen 1991; Bradley and Dunlop 2005; Chen and Nath 2008; Melville et al. 2004)

*Table 2. Definition of constructs in the research conceptual model*

Proposition	Description	Explanation
P1	Knowledge leakage risk through mobile devices informs the organizational knowledge leakage risk mitigation strategies.	Organizational risk mitigation strategies are designed according to the risk exposure and risk appetite (risk profile) of the organization. For instance, military organizations will have a different risk profile and, therefore, different mitigation strategy as compared to a not-for-profit organization (Baskerville et al. 2014)
P2	Human factors affect the knowledge leakage risk through mobile devices.	This proposition refers to constructs such as self-efficacy, motivations, attitudes, personality traits, social norms, peer influence that affect the behaviour and perception of users when interacting with IS (Ajzen et al. 1991)
P3	Enterprise factors determine the knowledge leakage risk through mobile devices.	This refers to organizational resources (Barney 1991) such as organizational structure, policies and rules, workplace practices, and culture which condition the perception of IS phenomena (Melville et al. 2004; Sveen et al. 2009; Whitman, Michael and Mattord 2011).
P4	Technological factors modify the knowledge leakage risk through mobile devices.	Technological controls such as firewall, IDS, and compartmentalization lead to a diminished KL risk, particularly, when neglecting human aspects such as intentions and compliance (Bulgurcu et al. 2010; Herath and Rao 2009; Pahnla et al. 2007).

*Table 3. Conceptual Model Propositions*

### 3.1 Knowledge Leakage Risk & Organizational Knowledge Leakage Risk Mitigation Strategies

The resource-based view (RBV) highlights the importance of protecting resources and capabilities to sustain competitive advantage in organizations (Leonard-barton 1992). In this perspective, the organizational knowledge capability needs to be protected, and the knowledge leakage risk (KLR) associated to this asset requires assessment. However, the risk evaluation process is a subjective exercise that leads to a perceived KLR characterized by the impact and likelihood of leakage happening (ISO/IEC 27005:2011 2011). As a result, the risk treatment involves selecting one or more options for modifying the risk impact or probability. Such treatment includes implementing controls and strategies to address the residual risks that are suited to the risk profile of the organization, environment and resources. Such arguments lead to our first proposition, which serves as the

foundation to examine the role of perceived KLR to firm's strategy in developing organizational mitigation controls:

**Proposition 1.** *The knowledge leakage risk through mobile devices informs the organizational knowledge leakage risk mitigation strategies.*

This proposition aims to answer our research question: *How does the knowledge leakage risk through mobile devices inform organizations' mitigation strategies?*

### 3.2 Human, Enterprise and Technological Factors

As discussed previously and expanding on RBV and contextual framework, previous studies have evaluated a considerable number of organizational characteristics as determinants of competitive advantage, which in turn have been classified within the broader category of basic competences or influencing factors (Chen and Nath 2008; Leonard-barton 1992):

1. Human factors, which include among other things, a firm's knowledge and skills, accumulated either through training of its workforce (Teece 2007) or as a result of the experience acquired over time (Ristovska et al. 2012). Individual competences (personal context) as well as group competences (social context) are part of the key internal capacities of a firm to develop capabilities. However, such competencies also affect the decision making and critical protection action processes (Ajzen 1991) such as risk evaluation. The above discussion leads to:

**Proposition 2.** *Human factors (**personal** and **social** contexts) affect the knowledge leakage risk through mobile devices*

2. Enterprise factors, which include the organizational resources (internal conditions) such as structure, policies, rules, workplace practices and culture (organizational context); and the environment (external conditions) in which the organization operates and interacts with other organizations including its market, regulations, competitors and external resources (environmental context) (Melville et al. 2004). These factors determine the risk profile and appetite of the organization, which leads to our third proposition:

**Proposition 3.** *Enterprise factors (**environmental** and **organizational** contexts) determine the knowledge leakage risk through mobile devices*

3. Technical factors, which include infrastructure, shared technology, system integration, technology services across and outside the organization (technological context) (Melville et al. 2004) in conjunction with mobile devices (device context) used by workers to perform their activities (Chen and Nath 2008) enable the sharing and creation of knowledge. Although, the technical capabilities facilitate the conditions for knowledge accumulation, it can also pose a challenge for knowledge protection due to the excessive reliance on technical controls to safeguard organizational knowledge assets, leading to a false sense of security. Hence we propose:

**Proposition 4.** *Technological factors (**device** and **technological** contexts) modify the knowledge leakage risk through mobile devices*

## 4 Conclusion and Future Work

The results of this study are expected to have both practical and theoretical implications. This study is expected to contribute to IS security research by proposing a comprehensive conceptual model which will be empirically tested in later phases and will investigate the determinants of knowledge leakage risk through mobile devices in knowledge-intensive organizations operating in highly competitive environments. Our study is also expected to provide meaningful implications for security and knowledge managers in organizations to improve risk mitigation strategies associated to knowledge leakage.

In today's security landscape, mobile devices present some new threats to organizations' mobile device security and knowledge management strategy. Effective KLR mitigation strategies will help organizations better manage those devices in their environment protecting their organizational knowledge. This study is the first attempt to view KLR through mobile devices in organizations from a mobile usage perspective using a contextual approach combining human, enterprise and technological dimensions. By analyzing the determinants that influence the knowledge leakage risk through mobile devices in organizations, addressing not only technological aspects but also human and organizational aspects, the proposed model presents a better way to design mitigation strategies and leakage risk controls (i.e., formal, informal and technological) that is more likely to be accepted and followed by employees (Dhillon 2007).

We have proposed a conceptual model which will be tested at a later stage and seeks to explain how the knowledge leakage risk is influenced by human, enterprise and technological factors and how such KLR informs organizations' mitigation strategies. Empirical confirmation and refinement of the research conceptual model is an important future research direction to follow. In order to test our model, we will conduct a qualitative exploratory and explanatory research approach since knowledge leakage through mobile devices in organizations is a social phenomenon that includes the human perspective and we seek to explain the factors that underlie this particular social IS phenomenon based on the proposed conceptual model (Neuman 2006; Venkatesh et al. 2013).

The model will be qualitatively tested using the different usage context factors to develop a set of risk scenarios that characterize the combination of different contexts and their impact on leakage using the methodology followed by D'Arcy et al. (2009). The study will be comprised of three phases: a pilot study, interviews and a focus group, and case studies. Findings drawn from the first study (i.e., pilot study) will inform the second study. The target organizations for this study will be knowledge-intensive (innovative) organizations in Australia that operate in highly-competitive environments that need to protect their knowledge/information in order to sustain their competitive advantage, e.g., pharmaceuticals, telecommunications, software and service companies.

In the first phase, we will identify different scenarios that exemplify the different mobile usage contexts found in the literature and evaluate mechanisms for addressing the risk elicited from such factors which result in better mitigation strategies and controls. In this phase, 30 interviews with knowledge managers (15) and security experts (15) will be conducted. The objective of this phase is to better conceptualize the different constructs and investigate how such factors characterize KLR mitigation strategies using the conceptual model as reference to build the risk scenarios upon which the mitigation strategies used by organizations will be gathered.

In the second phase, we will conduct two focus groups, one with knowledge managers and other with security managers from different knowledge-intensive sectors in Australia to further improve the concepts and the underlying propositions in the model. The reason as to why knowledge managers will be separated from security managers in the focus groups, is the contrastingly opposing views in relation to knowledge sharing that knowledge and security managers have will hinder the progress of the discussion, should they be in the same group (Ahmad et al. 2014; Manhart and Thalmann 2015). The goal of this phase is to develop specific-sector insights (i.e., private, military, governmental and not-for-profit organizations) in order to contrast different industries.

In the third phase, we will conduct three in-depth case studies, following Yin's (2003) methodology, in different types of knowledge-intensive organizations (e.g., private, military, governmental and not-for-profit organizations) which operate in highly-competitive environments in order to validate our findings and the proposed conceptual model from our previous phase and further refine the model. The objective of this phase is to generalize the findings of this research.
