Abstract

This paper reports from a systems development research tradition in which emphasis is put on relating research activities to practice and on establishing fruitful collaboration between groups of researchers and practitioners. The paper describes and evaluates a specific research project in which a large group of researchers and practitioners worked together to understand, support, and improve systems development practice over a period of three years. The case is used to reflect on the research goals, approaches, and results involved in this tradition for researching systems development practice. A combined approach—based on action research, experiments and conventional practice studies—is suggested as one practical way to strike a useful balance between relevance and rigor in practice research. The paper is concluded with a more general discussion of the relation between research and practice together with advice on how to design collaborative research efforts.

Keywords

Systems development, research, practice, collaboration.

1. Introduction

The Information Systems discipline has for quite some time been preoccupied with improving the ways in which we do research. This concern for research methodology has played a major role in maturing the discipline and it has resulted in a rather rich discussion of different approaches (McFarlan 1984, Mumford et al. 1986, Boland et al. 1987, Galliers et al. 1987, Galliers 1991, Cash et al. 1989, Nissen et al. 1991, Lee et al. 1997). In our efforts to become a respected research discipline we have also established an impressive portfolio of scientific journals and international conferences that serve as the primary media for publishing research findings. Our discussions of research methodology have therefore concentrated on how to support researchers in designing dedicated research activities that lead to good scientific papers.

A number of scholars within our discipline have recently made a strong plea for more relevance without abandoning rigor (Applegate 1999). Benbasat et al. (1999) recommend ways to increase the relevance of our research by reconsidering topic selection, the purpose and content of the articles we write, the article's readability, and the reviewing process. Davenport et al. suggest more radical interventions that challenge core academic values around research rigor, publication outlets and audiences, and consulting (1999). Lyytinen (1999) supports such a broader view and encourages us to critically rethink the institutional policies and incentive schemes that govern research, the organisation of research groups, the professional image of Information Systems researchers, and last but not least the ways in which we study practice. And Lee (1999) argues for a need to go beyond a positivistic research tradition.

This paper addresses many of these concerns by reporting from a research tradition that for some years have studied practice in close collaborations between groups of practitioners and researchers. Such a collaborative approach introduces new interpretations of the relation between research and practice, it raises many practical problems and conflicts, and it is not easily implemented into any institutional setting. The purpose of the present argument is therefore not to criticise well-established research traditions. Rather it is to critically rethink key issues in designing practice research based on experiences from a particular

tradition in which relevance is emphasised without abandoning rigor.

Starting out from research methods, or from the point of view of writing scientific papers, invites us to think in terms of choosing between different research methods (see for example Galliers et al. 1987, Galliers 1991). This viewpoint is extremely useful when one wants to understand the variety and the relative strengths and weaknesses of available research methods. But when designing and organising research projects based on collaboration with practitioners the challenge is not so much which methods to choose. Rather it is to find practical ways to combine qualitatively different research approaches to support the diverse, and partly contradictory goals involved in such an effort. In the following I in favour of such a combined approach—based on action research, experiments, and conventional practice studies—as one practical way to strike a useful balance between relevance and rigor in practice research.

Section 2 presents and discusses a particular research project in which a large group of researchers and practitioners worked together to understand, support, and improve systems development practice based on the so-called Software Process Improvement (SPI) paradigm (see e.g. Emam et al. 1998, Humphrey 1988, 1989, Kuvaja et al. 1994, Paulk et al. 1993). Based on this case and on the related tradition for doing practice research, I review classical issues and state-of-the-art literature related to research goals (Section 3), research approaches (Section 4), and research results (Section 5). Section 6 examines the underlying view of the relation between research and practice and provides advice on how to design useful collaborations between researchers and practitioners. While the issues raised are of interest to Information Systems research in general they are discussed based on experiences from the particular field of systems development.

2. Research Practice

The SPI Project was a research collaboration involving practitioners from four software organisations and researchers from universities and technology institutes (Johansen et al. 1998). The collaboration ran over three years (1997-1999) with a 4 million US\$ budget of which half was financed by the Danish Ministries of Commerce and Research while the other half was sponsored by the participating software organisations.

The project involved more than 10 researchers each spending between 25% and 75% of their time on the project and it involved 3-7 practitioners from each organisation as active members of the research project.

Establishing such a research effort is in no way easy. We had good contacts to all levels of the four participating organisations, national research programmes provided funding to make researchers collaborate more closely with industry, and the particular theme of the project, i.e. SPI, was known to provide attractive opportunities for software organisations. Finally, we had considerable experience in working closely with practitioners and our institutional setting was positive towards collaboration with industry. Our approach to research has grown out of the Scandinavian trade union research tradition (Nygaard et al. 1975, Bjerkness et al. 1995), it has later been inspired by Checkland's approach to action research (Checkland 1981, Checkland et al. 1990), and it has been adapted and developed since the early 1980's to suit the study of systems development practice (Mathiassen 1998a, 1998b).

The industry related mission of the project was: to systematise SPI knowledge in Danish companies, to tailor and further develop the most promising models for SPI so they apply to the Danish software industry, to develop frameworks for managing, organising and implementing SPI activities in Danish companies, and finally to communicate and publish knowledge about SPI to Danish companies. These missions were addressed through research efforts in which the following research questions were addressed:

Evaluation: How can we interpret or assess an organisation's capability to develop systems, identify appropriate improvement areas and strategies, and measure the effect of the implemented improvement?

Modelling: How can we model systems development processes, the conditions under which they are performed, and their capability to develop quality systems?

Improvement: How can we manage, organise, and carry out initiatives that in a sustainable way improve an organisations capability to develop quality systems?

To meet this diverse set of industry and research related objectives the project was organised as a loosely coupled system of interacting agendas each addressed by a dedicated forum of actors. The overall organisation of the project is illustrated in Figure 1.

Figure 1: Overall research organisation.

First, a local research group was established to study software process improvement in each of the four software organisations, see Figure 2. This group worked tightly together with the local management (both informally and formally through a steering committee), the local SPI group, and the ad-hoc projects that were established to implement specific improvement initiatives. Each research group included 3-7 practitioners from the software organisation (normally the SPI group) and 3-4 external researchers. The research group met 8-10 times a year and followed the SPI initiative closely. The group supported the software organisation in adapting and using improvement approaches; it participated in some of the organisation's dedicated improvement projects; and it continuously evaluated the way in which SPI knowledge was adapted, used, and further developed within the organisation.

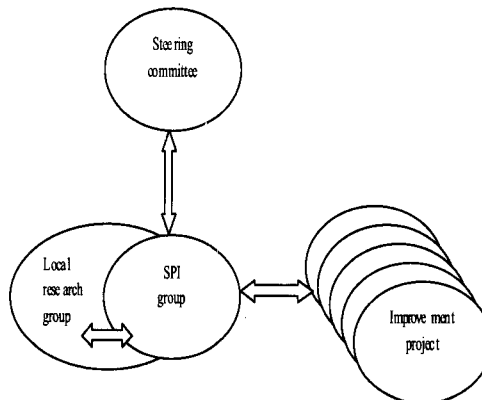

Figure 2: Local research organisation.

Second, a plenary consisting of the four local research groups was formed to support interaction between the involved researchers and practitioners. This plenary of 25-35 persons met twice each year in 2-day workshops where: experience and knowledge was exchanged across the companies, new knowledge on process improvement was presented, ideas related to specific improvement areas were discussed, and experiences were interpreted and put into perspective through general discussions of software development, software management, and organisational learning and change.

Third, a nation-wide network was formed to support software process improvement initiatives in other organisations. More than 50 companies and 80 individuals participated in this network that met for 1-day seminars 3-4 times a year. The project also organised or participated in a number of conferences on SPI targeting the Danish software industry.

Last, but not least, a researchers' forum was formed to stimulate publication of results and collaboration between the involved researchers. The researchers' forum met for half a day 6-8 times a year: to identify emerging research themes, to plan dedicated research initiatives, to form new patterns of collaboration between researchers, to discuss research approaches, to present and evaluate preliminary results, and to discuss relevant theoretical frameworks and related research. The researchers' forum also served as a means to support close collaboration with a number of international research colleagues. Their participation was established to improve the research process by including experiences from similar research projects and knowledge from relevant reference disciplines.

From the point of view of the individual researcher this organisation constituted a collaborative space in which dedicated research initiatives and shifting patterns of collaboration took shape as the process unfolded. Typically, each researcher participated in two local research groups, they took part in all plenary meetings, and they were actively involved in the researchers' forum. When adding additional ad-hoc meetings related to preparation of seminars and workshops, planning of joint publications, and supervision of PhD thesis work each researcher would typically participate in 1-3 joint activities each week during the three year course of the project. The number of shared obligations, some of a rather practical nature, that follow from participating as a researcher in such a collaborative effort is therefore extremely high. But

I will argue that the opportunities to create relevant research results are at the same time extremely good.

3. Research goals

Collaborative research involving both researchers and practitioners must serve different interests. In the SPI project there was an industry-related mission together with a set of research goals; there is also an ambition to add to the body of knowledge within the systems development profession while at the same time advancing practices in each of the participating organisations. Collaborative practice research is in this way constantly confronted with dilemmas between practice-driven and research-driven goals and between general and specific knowledge interests. It is well-known that researchers in such situations easily turn into consultants (Baskerville et al. 1996a) and it was therefore not surprising that we had to actively promote our research interests in the SPI project. SPI efforts are both demanding and exciting so the researchers were constantly encouraged to engage themselves in the practical struggle to make things happen and succeed in the four organisations. In response to this pressure we build a strong sub-culture around the researchers' forum to maintain critical reflection, publication, and research methodology as key issues.

Underlying the specific goals of a collaborative practice research effort we find a deeper level of related research goals and activities. These goals can be expressed in terms of the types of knowledge that the effort intends to develop. Adapting the framework offered by Vidgen et al. (1997) we can distinguish between different types of knowledge as illustrated in Figure 3 (Mathiassen 1998a, 1998b). The arrows inside the triangle represent distinct, and in some respects divergent, research activities through which each type of knowledge is developed. First, to develop our understanding of systems development we must engage in interpretations of practice. Second, to build new knowledge that can support practice we must design normative propositions or artefacts, e.g. guidelines, standards, methods, techniques, or tools. Third, to learn what it takes to actually improve practice we must engage in different forms of social and technical intervention. Most Information Systems research restricts itself to understanding and supporting practice. A commitment to improve practice is the distinguishing feature of collaborative practice

research and of action research in general (Baskerville et al. 1996a).

The three goals are distinct and can be pursued in isolation. But that would seriously reduce the opportunities to learn about practice. The triangle symbolises that the involved activities presuppose each other: we reach a deeper understanding of practice as we attempt to change it; we need to understand practice to design useful propositions; and, the propositions and our interpretations of practice are ultimately tested through attempts to improve practice. This unity of the goals is a simple expression of the elements in organisational learning and change: to appreciate the situation—to invent new options—to change the situation. We find these elements in different forms and relations within theories of the field (e.g. Argyris et al. 1978, Schein 1985) and in practical approaches as well (e.g. Checkland 1981, Checkland et al. 1990, Davenport 1993).

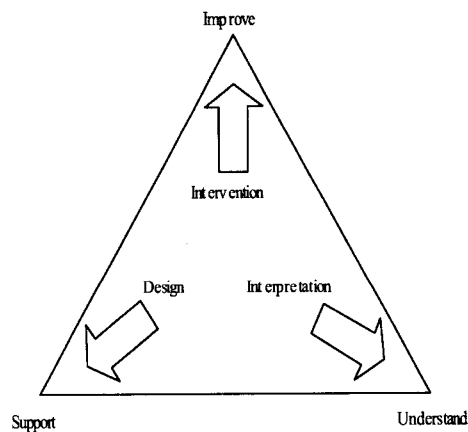

Figure 3: Research goals and activities (adapted from Vidgen et al. 1997).

The research goals apply to different levels of practice. First, they apply to systems development. Due to the complex and dynamic nature of the discipline systems developers need to practice reflection-in-action (Mathiassen 1998a, 1998b, Schön 1983). They must interpret the situations in which they find themselves (understand); they must develop what-if scenarios to reflect on opportunities for action (support); and they must enact some of these to establish and maintain satisfactory working situations (improve). Second, these goals and activities correspond closely to the main ingredients involved in dedicated improvement

activities as expressed in the so-called IDEAL model (McFeeley 1996) for SPI (Initiate improvement effort, Diagnose current practices and form strategy for intervention, Establish specific improvement projects, Act to improve, and Learn from the initiatives). The IDEAL process represents a specific way to enact the general learning cycle expressed in the triangle: to appreciate the situation—to invent new options—to change the situation and so on. Third, the triangle expresses the types of knowledge and activities involved in collaborative practice research. Practice, improvement of practice, and practice research are in this way both similar and different in nature. We will further explicate the relation between them in Section 6.

A closer look at the SPI project can illustrate how the goals unfold in research practice. One of the fundamental ideas in SPI is to use data-driven intervention, i.e. to base decisions on new improvement initiatives on systematically collected data about current practices. There was therefore a natural focus in the SPI project on activities aimed at evaluating practice. Hence the question: how can we understand, support, and improve the ways in which we evaluate systems development practice as part of SPI efforts? Various types of assessments were carried out to evaluate present practices against general norms (Andersen et al. 2000, Iversen et al. 1998a), problem diagnosis was used to appreciate what the involved actors considered to be critical problems in present practices (Iversen et al. 1998b), defect reports were analysed to identify patterns of problematic behaviour (Vinter 1998), and metrics programs were implemented to learn about the effect of the improvement initiatives (Iversen et al. 2000). Each of these contributions gave different priority to the three research goals. Some (Iversen et al. 1998a, Iversen et al. 2000) focused on interpretations of practice (understand) and suggested lessons to guide SPI efforts (support). Others (Andersen et al. 2000, Iversen et al. 1998b, Vinter 1998) were driven by specific ideas on how to evaluate systems development practice (support) and these were then tried out and evaluated in practice (improve and understand).

4. Research approaches

Turning to research approaches we find a multiplicity of general approaches to Information Systems research

together with extensive discussions of their strengths and weaknesses (McFarlan 1984, Mumford et al. 1986, Boland et al. 1987, Galliers et al. 1987, Galliers 1991, Cash et al. 1989, Nissen et al. 1991, Lee et al. 1997). In addition, we find a more specialised discussion of approaches to systems development research (Basili et al. 1984, 1986, Nunamaker et al. 1991, Cotterman et al. 1992, Wynekoop et al. 1993).

The main concern in collaborative practice research is to establish well functioning relations between research and practice. This is, however, far from easy to achieve. Practitioners must, on the one hand, agree to become objects of study. Practitioners must accept to have meetings tape-recorded, they must engage in critical reflections of their practices, and they must be willing to report weaknesses and failures of their efforts. Researchers must, on the other hand, commit themselves to improving practice and adopt flexible research approaches as practice changes and new priorities emerge.

Ideally, we want the research process to be tightly connected to practice to get first hand information and in-depth insight. At the same time, we must structure and manage the research process in ways that produces rigorous and publishable results. Unfortunately, these two fundamental criteria do not always point in the same direction. The dilemmas related to fulfilling the two criteria can be expressed by distinguishing between three basic research approaches as illustrated in Figure 4 (Munk-Madsen 1986, Nunamaker et al. 1991, Wynekoop et al. 1993, Mathiassen 1998a, 1998b). Each of these approaches can be practised in a variety of ways and they all contribute to the building of knowledge on systems development.

Action research provides optimal access to practice, but it is quite difficult to control the research process. The researcher is involved in practice situations in close collaboration with practitioners and the research agenda is therefore strongly dependent on how practice evolve. The research activity can focus on the systems being developed, on the development processes, or on both. The strength of this approach is the strong integration of research and practice: practitioners are involved in the research process and researchers gain first-hand experience. The most significant weakness is the limited support provided to structure the research process and findings. Quite a number of recent papers have discussed the use of action research within Information Systems (Baskerville et al. 1996a, Lau

1997, Stowell et al. 1997, Mathiassen 1998a, 1998b, Avison et al. 1999, Nielsen 1999). But the actual use of action research to systems development is documented in relatively few sources (e.g. Kaiser et al. 1982, Mumford 1983, Parnas et al. 1986, Salaway 1987, Knuth 1989, Avison et al. 1991b, Bjerknes 1991, chapters 2, 10, 14, 18 in Mathiassen 1998b).

Experiments provides direct access to a practices that are controlled, or partly controlled, by the researchers. Such experiments can either take place in realistic settings as a field experiment or in laboratory environments. A key advantage with this type of research is that the research process can be designed to focus on specific questions and issues. The disadvantage, as compared to action research, is the weaker relation to practice. Experiments are more commonly used in systems development research and a number of contributions have been reported based on this approach (e.g. Boland 1978, Vitalari 1983, 1985, Boehm et al. 1984, Floyd 1986, Selby et al. 1987, Guindon et al. 1987, Baskerville et al. 1996b, chapters 3, 7 in Mathiassen 1998b).

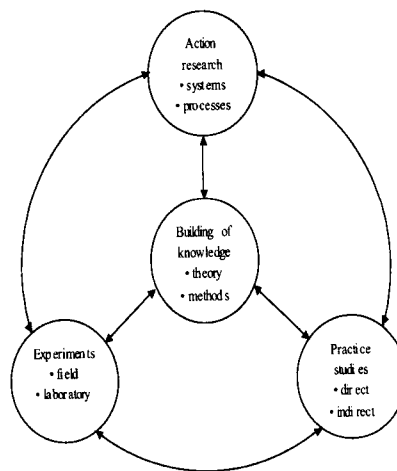

Figure 4. Approaches to study systems development practice (adapted from Nunamaker et al. 1991).

Practice studies cover a wide variety of approaches to study systems development without active involvement of the researchers. Some approaches study practice directly, e.g. field studies and case studies, whereas others are indirect based on people's

opinions and beliefs, e.g. surveys or interviews. The strengths of this approach are that it focuses on practice and that it provides the researchers with a vast repertoire of techniques to structure the process and the findings. The weakness is that it separates research from practice. The researchers observe and interpret the actions and beliefs of practitioners and the practitioners do not take active part in the research process. Most of the empirical literature on systems development is based on practice studies (e.g. Benbasat et al. 1980, Boland et al. 1982, Markus 1983, McKeen 1983, White 1984, Gould et al. 1985, White et al. 1986, Necco et al. 1987, Krasner et al. 1987, Elam et al. 1987, Curtis et al. 1988, Boehm et al. 1988, Aaen et al. 1992, Stolterman 1992, Bansler et al. 1993, Kozar 1993, Madabushi et al. 1993, Waltz et al. 1993, Ciborra et al. 1994, Tan 1994).

The SPI project is basically organised as an action research effort to gain optimal conditions for interacting closely with practice and to support close collaboration between practitioners and researchers (Baskerville et al. 1996a). This basic approach is, however, complemented with experiments and with practice studies to establish a more complete and solid foundation for producing rigorous research results. Such a combined strategy supports the variety of research goals discussed above and it compensates for the greatest weakness of action research: the limited support that it provides for structuring the research process and findings. The action research approach is in the SPI project implemented through the local research groups, see Figures 1 and 2. The agendas of these groups reflect the local SPI initiatives, and the groups serve as a forum for evaluating SPI practices, for experimenting with new or modified approaches, and for learning about the impact of SPI approaches on practice. Field experiments are then staged as dedicated research initiatives within this setting and focused practice studies are initiated to learn about selected SPI practices and their impact on the organisation. Some examples will illustrate this combined approach.

The major challenge faced by the SPI initiative in one of the participating organisations was to motivate the systems developers, and in particular the project managers, to commit themselves to improvement efforts. Traditional SPI initiatives are based on normative models (e.g. Emam et al. 1998, Kuvaja et al. 1994, Paulk et al. 1993) but none of these

models were considered useful by the SPI group or the developers. The SPI group therefore decided to use problem diagnosis techniques rather than assessments based on general models to learn what the developers considered to be key problems. This research initiative is documented in (Iversen et al. 1998b) and it is primarily based on action research as proposed by Checkland (Checkland 1981, Checkland et al. 1990).

Each improvement project that is initiated as part of an SPI initiative is facing a complex and often quite risky task, for example to develop, implement, and institutionalise processes to support subcontract management in the organisation. The SPI group in one of the organisations wanted to develop tools that could support specific improvement projects in managing risks thereby minimising the chance of failure. A dedicated risk management tool for improvement projects was therefore developed based on the experiences from that organisation in combination with insights from the SPI literature. The resulting tool is documented in (Iversen et al. 1999) and the underlying research approach is primarily a field experiment.

Some events during the course of the SPI project were considered so interesting that they attracted special attention. One such case was the implementation of a metrics program to help the organisation measure the effects of their improvement efforts. A focused study of this particular case was based on the 'natural traces' of the SPI program such as project plans, meeting minutes, and memos. In addition to this, we tape-recorded the monthly meetings in each local research group as well as some of the working sessions and workshops to collect supplementary data to be used in dedicated and focused research initiatives. The relevant segments for the metrics program were transcribed. The case and the lessons learned are published in (Iversen et al. 2000) based on a combination of direct and indirect practice studies.

We see in these examples how a variety of research approaches are used in dedicated research initiatives within the larger project. The SPI project can from this point of view be seen as a collaborative space in which specific, and dedicated research initiatives are formed to report 1) key lessons from selected parts of the action research activities, 2) proposals based on field experiments that are designed to provide local support, and 3) insights from practice studies of events that emerge as interesting or surprising cases. These three types of research initiatives are exemplified

above and they are initiated based on the agendas of the local research groups, see Figure 1. The agenda of the researchers' forum is, however, broader. It includes classical concerns, in which SPI is seen as one instance of technology related organisational change, and it involves theoretical issues and the use of reference disciplines. Insights from practice were therefore also used in the SPI project as inspiration for theoretical studies. A few examples illustrate these theoretical activities.

The SPI literature is extensive, but rather practical with only little concern for fundamental research questions. In the SPI project we had many discussions on the identity and boundaries of the SPI approach as described in the literature. We found no explicit shared understanding of SPI as a strategy for change in systems development organisations. Based on our practical experiences we therefore decided to survey the SPI literature to explicate important underlying assumptions and related strategies for change (Aaen et al. 2000).

There are also only few and rather weak relations between the SPI literature and relevant reference disciplines. It is therefore interesting to interpret SPI experiences using contemporary frameworks from other research areas. One such example is the use of Nonaka's theory of knowledge creation (Nonaka 1994) to understand better how tacit and explicit forms of knowledge can be combined in software organisations and how one can support interaction between individual, group, and organisational knowledge creation processes (Arent et al. 2000). Such studies serve to interpret and inform SPI practices, and they often provide interesting examples for the reference discipline in question.

Other theoretical contributions from the SPI project are based on subjective/argumentative approaches (Galliers et al. 1987, Galliers 1991). SPI is typically based on a rather narrow view of the systems development process, e.g. from a contract is signed until a software system is delivered, and the main concern is to improve processes within the software organisation. Bjercknes et al. (2000) reflects on the nature of well-functioning customer-supplier relations, it evaluates those SPI models that are concerned with improved customer relations, and it proposes specific initiatives to improve the collaboration between customer and supplier organisations. Such initiatives were subsequently initiated in one of the participating

organisations. The research was hence developed as inspiration for innovative activities that could lead to alternative SPI strategies.

5. Research results

Collaborative practice studies, as I have discussed them here, are both practice- and research-driven and they serve general knowledge interest as well as knowledge interests that are specific for the participating organisations. The results of such efforts are therefore of a more diverse nature than those of conventional research projects.

There was a strong inclination in the SPI project to focus on practical results. The rationale to participate was, from the point of view of the software organisations, to engage in collaborative activities that could lead to improved systems development performance and that could stimulate learning within the organisation. It goes without saying that actual improvements in processes, infrastructure, and competencies were the key success criteria for the local SPI groups. This constant pressure to focus on practical results implies that research results tend to have secondary priority. The project was therefore from the very start based on a shared commitment, between the involved organisations, the individual practitioners, and the researchers, to build new knowledge that could be published as a contribution to the body of knowledge on systems development. This commitment was maintained by having research issues integrated into the agendas of all groups in the project organisation, cf. Figure 1.

Conventional research publications played an important role in the SPI project. Three Ph.D. studies were carried out as part of the project and more than 30 papers were published addressing a variety of issues. The important difference in relation to more conventional research projects was that practitioners were included as an important target group for the project. First, more than 10 papers with results from the project were published at conferences or in journals mainly for practitioners (e.g. Johansen et al. 1998, Vinter 1998, Jakobsen 1998). Second, it was decided to publish key lessons from the project in a book called "Learning to Improve". Each chapter in the book presents lessons on SPI from the project, it is written for practitioners to read, the foundation is academically sound based on documented research results from the

project, and most of the chapters are co-authored by researchers and practitioners. Papers published in IEEE Software are used as model examples for each chapter and an editor from this journal is engaged to guide the authors and facilitate the editing process.

“Professional Systems Development” (Andersen et al. 1986, 1990), “Quality Management in Systems Development” (Bang et al. 1991), and “Object Oriented Analysis and Design” (Mathiassen et al. 1997) are earlier examples from previous projects illustrating that publication for practitioners is given high priority in this research tradition. There is a sound rationale for pursuing such a strategy in practice research. The researchers are constantly challenged to develop and express results they believe to be useful in practice. Practitioners study the contributions, they attempt to use them, and that reveals strengths and weaknesses of the published results. The research contributions are in this way instrumental in establishing and maintaining a dialogue between research and practice that goes beyond specific research projects. Such a dialogue serves to test and further develop new knowledge, it plays a major role in developing higher education within our discipline, and it helps build an image of the researchers as actively contributing to improved professional practices. This, in turn, makes it considerably easier to establish new collaborations with practitioners.

Unfortunately, such research contributions are given quite low, and in some cases no, priority in making career decisions within the established research community. The incentive to publish for practitioners is therefore minimal, and a simple cost/benefit analysis will lead most researchers to the conclusion that it is not worthwhile to become engaged in collaborative practice studies. In that way, we risk isolating ourselves as an appendix to the Information Systems profession instead of being a major force in strengthening its position in society. We should not, of course, stop our efforts to mature as a respected research discipline with high quality journals and research conferences. But we should take care to combine these ongoing initiatives with modified incentive schemes, intensified collaboration with practitioners, and more publications that address practical concerns. That will help us develop new knowledge that prove to be relevant and it will strengthen our position within the profession and society in general.

6. Research and Practice

Collaborative practice research is not merely a way to organise and conduct research. Underlying the specifics of the SPI project is a coherent view of practice, of research, and of the relations between the two. This view is part of a research tradition that has been developed over the past twenty years. The tradition has been discussed as “the ordinary work practices approach” (Hirschheim et al. 1992) or “the professional work practices approach” (Hirschheim et al. 1995a, 1995b, Iivari & Lyytinen 1997). I have presented the underlying perspective as “Reflective Systems Development” (Mathiassen 1998a, 1998b) to acknowledge the relation to Schön’s ideas on how professionals think in action (1983, 1987) and to stress the intrinsic relation between research and practice. The SPI project should be seen as an effort to further develop this tradition by addressing some of its weaknesses, e.g. a too simplistic view of what it takes to improve practice and lack of an explicit notion of what it means to change practices to the better (Hirschheim et al. 1995a, 1995b).

Reflective Systems Development is illustrated in Figure 5 based on Checkland’s notion of the experience-action cycle (Checkland et al. 1990). The challenges and opportunities involved in systems development practice are considered the starting point for systems development research. Research activities yield experience-based knowledge that leads to new, and hopefully improved, practices. The knowledge that is developed in this process is both interpretive and normative. Part of it remains local, individual, and even tacit, while other parts are explicated and made publicly available as systems development guidelines, professional books, and research contributions. The research activity is primarily informed by systems development practice, but supported by various reference disciplines (e.g. design theory, organisation science, management science, and philosophy), and by dialectic reflections that help us understand change and the contradictory nature of our discipline (Robey 1995). The reference disciplines and dialectics encourage the researchers to go beyond the limited perspectives of approaches like SPI and to frame their thinking and results in ways that contribute to the building of research-based knowledge.

Reflective Systems Development expresses one, coherent view of practice and research with

two different modes of inquiry, a research and a practice mode. This is expressed in Table 1 based on Checkland's ideas on how intellectual frameworks are used in relation to specific application areas (Checkland et al., p. 283). The table explicates the different, but related purposes of research and practice, the underlying intellectual frameworks, the type of process in which they are applied, and the shared arena to which they are applied.

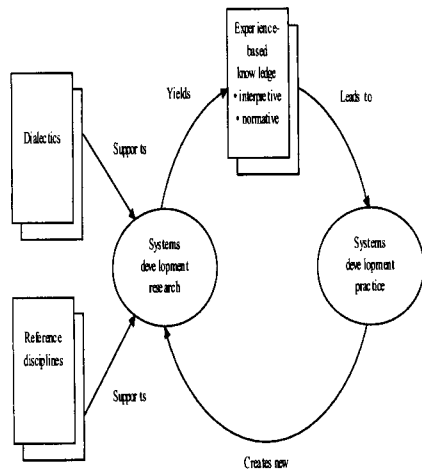

Figure 5. Reflective Systems Development (Adapted from Checkland et al. 1990).

Research becomes in this view an activity in which practitioners (can) participate and collaborate with researchers. "The practitioner does not function as a mere user of the researcher's product. He reveals to the reflective researcher the ways of thinking that he brings to his practice, and draws on reflective research as an aid to his own reflection-in-action. Moreover, the reflective researcher cannot maintain distance from, much less superiority to, the experience of practice . . . he must somehow gain an inside view of the experience of practice" (Schön 1983, p. 323). This view of research implies and builds on a complementary view of practice in which reflection and learning are key elements. Systems developers must, in addition to mastering a repertoire of general methods and tools, know how to cope with the specific environment in which they work. Many situations involve uncertainty, instability, uniqueness, and contradictions and they require an ability to go beyond the relatively safe territory of

general professional knowledge. Systems developers must open their minds and engage in reflections and dialogues to generate the necessary insights into the situation at hand.

	Research	Practice
Purpose	to develop knowledge to understand, support, and improve practice as part of the ongoing professional development	to develop computer-based information systems as part of the ongoing transformation of organisations and society
Frame work	dialectics reference disciplines	systems development theory systems development methods
Process	action research	reflection-in-action
Arena	systems development practice	systems development practice

Table 1. Reflective Systems Development as an approach to research and practice.

The SPI project is from this point of view an attempt to practice Reflective Systems Development as a close collaboration between researchers and practitioners. I have discussed the project from a researcher's perspective and in the process provided concepts and experiences that can be used to organise similar initiatives. The discussion can be summarised as a number of lessons.

Lesson 1: Implement a full learning cycle of understanding, supporting, and improving practice. Understanding, supporting, and improving expresses the basic knowledge interests involved in studying practice. Dedicated research initiatives will have different emphasis, but it is important to organise the overall project so that it includes full learning cycles in which our understanding of present practices are confronted with explorations of possible alternatives to form new, and hopefully improved, practices.

Lesson 2: Organise the project as a loosely coupled system of related agendas. Research collaboration with practitioners involves a multiplicity of partly contradictory goals. Research projects should be organised to support diversity, but at the same time function as a shared space in which dedicated research initiatives can be formed as new opportunities emerge. It is particularly important to have separate, interacting agendas for local involvement and detached research.

Lesson 3: Combine action research, experiments, and practice studies. Action research should be used as

the basic form to establish a close relation to practice. But whenever feasible and useful it should be supplemented with experiments and practice studies. Such a combined strategy supports the variety of research goals involved and it helps establish a useful balance between rigor and relevance.

Lesson 4: Establish a basic documentation system to support longitudinal practice studies. The danger in action research is to become too involved in the problems of practice. Longitudinal field research has been developed in response to this challenge emphasising the need to establish systematic documentation efforts involving in-depth interviews, documentary and archive data, and observational and ethnographical material (Pettigrew 1990, Nielsen 1999). Such a documentation system serves as the backbone for organising dedicated research initiatives that are focused on particular events.

Lesson 5: Facilitate collaboration in dedicated research initiatives. Research projects should offer opportunities for establishing shifting patterns of collaboration between the involved researchers and between researchers and practitioners. Such patterns are established as interesting issues emerge and new, dedicated research initiatives are formed. Each new initiative involves specific actors and is based on its own combination of research methods to suite the task.

Lesson 6: Combine scientific publication with publications targeting practitioners. Traditional research publications should be supplemented with publications that inform practitioners about research results. Such publications challenge the researchers

to evaluate the relevance of their efforts and they are instrumental in maintaining a dialogue between researchers and practitioners beyond the specific project.

Lesson 7: Engage yourself fully, but only for a while. Collaborative practice research as described here offers good opportunities to develop relevant research results. But it requires a dedicated effort involving both research work and organisational work. During a project it is necessary to spend a major effort on the collaboration. After the project it is advisable to return to a more traditional activity pattern, to reflect on the experiences from the project, and to publish more of the insights that were gained during the project.

These lessons are meant as inspiration for those that have the opportunities and the motivation to engage in collaborative practice research. Such efforts are, however, difficult to create and demanding to manage. This is partly because of the diverse and contradictory nature of the interests and goals involved. But it is in many cases also because our institutional settings and incentive schemes do not encourage researchers to engage in close collaboration with practitioners (Lyytinen 1999).

Acknowledgements

This research has been partially sponsored by the Danish National Centre for IT Research. I wish to thank the software organisations, practitioners, and researchers participating in the Danish SPI project. I also want to thank the associated editor and the anonymous reviewers for many valuable suggestions.
