Abstract
Information systems (IS) departments face many challenges in today’s rapidly changing environment. One approach to understanding the challenges faced by IS departments is to survey IS managers to elicit what they consider key issues. Key issues in IS management surveys have been conducted for many years in many nations and regions. However, most key issues surveys seem to lack a theoretical basis for the selection of key issues. Furthermore, most key issues surveys have used the Delphi technique in multiple rounds. Recently, the analysis of key issues in IS management has been extended by a multimethod approach using Q methodology and interpretive structural modeling. This paper presents methodological issues and choices for a planned survey on key issues in IS management in Norway in 1999. A three step procedure for key issues selection is introduced, and a multimethod approach for analysis is adapted. However, this research is at an early stage making the paper primarily serve as a basis for discussion and feedback valuable for future research.

Introduction
Information systems (IS) departments face many challenges in today’s rapidly changing environment. One approach to understanding the challenges faced by IS departments is to survey IS managers to elicit what they consider key issues (Watson et al. 1997). According to Niederman et al. (1991), the primary purpose of such studies is to determine:
• Which IS management issues are expected to be most important over the next three to five years and thus most deserving of time and resource investment.

• How much consensus exists about the relative importance of specific issues.
• Why some issues deserve more attention than others.

IS vendors, professional societies, consultants, educators, and researchers need to be aware of IS executives’ key concerns to serve their markets effectively:

Vendors can use this information to develop and market products and services. Professional societies can use this information to plan conferences and seminars as well as disseminate knowledge through their publications. Consultants can use this information to help accelerate the transfer of technology and management skills among their clients. Educators can use this information to develop programs and place their graduates. Finally, researchers can use this information to help guide their inquiry and improve understanding of critical managerial issues. Thus, the entire IS community needs to be aware of the issues that are judged to be of critical concern by its leading practitioners. (Niederman et al. 1991, p. 476)

Key issues in IS management surveys have been conducted for many years in many nations and regions. However, most key issues surveys seem to lack a theoretical basis for the selection of key issues (Watson et al. 1997). Furthermore, most key issues surveys have only used the Delphi technique in multiple rounds (e.g., Brancheau et al. 1996). Recently, the analysis of key issues in IS management has been extended by a multimethod approach using Q methodology and interpretive structural modeling (e.g., Morgado et al. 1995, 1998). This paper presents methodological issues and choices for a planned survey on key issues in IS management in Norway in 1999. However, this research is at an early stage making the paper primarily serve as a basis for discussion and feedback valuable for future research.

**Literature Review**

Over the past two decades, the Society for Information Management (SIM) in the United States has periodically surveyed its members to determine the most critical issues in IS management (Brancheau et al. 1996). Surveys were conducted in 1980, 1983, 1986, 1990 and 1994-95, representing a valuable resource for key issues insights in a time perspective. These SIM studies have had a significant influence on key issues studies in other countries (e.g., Dekleva and Zupancic 1996, Wang 1994). IS key issues studies have been conducted in Australia 1993, Canada 1995, Costa Rica 1997, Estonia 1993, Europe 1993, Guatemala 1997, the Gulf Cooperation Council 1992, Hong Kong 1993, India 1992, Indonesia 1996, Poland 1994, the Republic of China (Taiwan) 1990, Slovenia 1993, South Korea 1995, and the United Kingdom 1993 (Watson et al. 1997).  

The results of two recent key issues in IS management studies are presented in the following. The first study listed in table 1 is the most recent US SIM study (Brancheau et al. 1996), while the second study listed in table 2 is the result of an international comparison of several key issues studies (Watson et al. 1997).
While table 1 is based on a survey in the United States in 1994-95, table 2 is based on surveys in eleven nations and regions in 1988-92. Six issues are present in both lists: strategic planning, alignment, information architecture, data resources, human resources and software development. The top three issues in the US SIM study are not present on the international list at all: infrastructure, business process redesign and distributed systems. In a time perspective, eight out of ten issues in the 1994-95 US SIM study were present in the top ten list from 1990 (Niederman et al. 1991). The two new issues emerging from 1990 to 1994-95 were business process redesign and distributed systems.

Most key issues studies are primarily concerned with issues facing information systems managers in the private sector. Although the IS community may share a common set of concerns across private and public organisations, more can be learned by identifying issues in different sectors. For example, Swain et al. (1995) identified key issues in public management information systems as listed in table 3.

### Table 1. US SIM Issues in IS Management (Brancheau et al. 1996)

<table>

<td>Planning and implementing a communications system</td>
</tr>
</tbody>
</table>
Three issues are present in all three lists in tables 1, 2 and 3: strategic planning, data resources and software development. A description of these issues is provided in table 4 based on Branchieu et al. (1996).

**Key Issues Selection**

Some key issues appear to emerge quickly. The sudden prominence of business process redesign in table 1, for example, indicates that IS managers may be too willing to respond to a current hot topic, and their attention may be too easily diverted from fundamental, long-term issues (Watson et al. 1997). If asked today, many Norwegian IS managers would probably rank “Year 2000” as a key issue. The Year 2000 issue is, however, both a short-term problem and an issue which is part of a bigger problem of maintaining software. Hence, the selection of key issues for survey research is associated with several problems (Watson et al. 1997) as listed in table 5.

The lack of theory is a major concern. Watson et al. (1997) suggest that a sufficiently relevant theoretical model on which to base a new key-issues framework, should be identified. They discuss role theory, managerial IS competencies and general management practices as “redesign” approaches to potential new key-issues frameworks:

Advantages of the “redesign” approach include the possibility that the framework be complete, consistent, parsimonious, and both regionally and temporally stable. Disadvantages include the lack of continuity with previous studies and the danger that the issues might become so abstract that they would cease to have meaning to IS managers and executives, thus breaking an important link to practice. (Watson et al. 1977, p. 111)

**Improving IS Strategic Planning**

It has always been important to align long-range IS planning with strategic business plans. Rapidly changing business environments, increased involvement of end users, and accelerated technological change underscore the need to continue improving strategic planning skills.

**Making Effective Use of the Data Resource**

The organisation’s data resource is growing in size, complexity, and value. Despite this, it remains largely unrecognised, inaccessible, and underutilised. IS must develop a climate within its department and throughout the organisation which values the data resource as a corporate asset.

**Improving the Effectiveness of Software Development**

The application development backlog remains at unacceptably high levels. Traditional development methods and platforms are no longer satisfactory. New methods and platforms have not yet proven themselves. Sophisticated users are getting impatient. Improved effectiveness will be essential for next-generation applications.

Niederman et al. (1991) made a theoretical contribution by classifying key is-
sues along three dimensions and catego-

rising them into four groups. The three
dimensions were management issues

versus technology issues (M/T), plan-

ning issues versus control issues (P/C)

and internal issues versus external issues

(I/E). The four groups consisted of:

• **Business relationship:** These issues

deal with concerns external to the IS
department. They focus on managing

the relationship between IS and the

business. The group included data

resources, strategic planning, organi-
sational learning, IS organisation

alignment and competitive advan-
tage.

• **Technology infrastructure:** These

issues deal with technology con-
cerns. They focus on the integration

of technology components to sup-
port basic business needs. The group

included information architecture,
technology infrastructure, telecom-

munications systems, distributed

systems, and electronic data inter-
change.

• **Internal effectiveness:** These issues

focus internally on the IS function.

They are concerned with those

essential activities comprising the

bulk of the IS function’s work. The

group included human resources,

software development, applications

portfolio and IS effectiveness meas-
urement.

• **Technology application:** These

issues focus on the business applica-
tion of specific information technol-
gies. The group included CASE

technology, executive/decision sup-
port, end-user computing and image

technology.

<p>| <strong>TABLE 5. Key Issues Selection Problems</strong> |</p>
<table>
<thead>
<tr>
<th><strong>Problem</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
</table>
| Time | Key issues change over time, critical issues in the early 1990s differ from criti-
cal issues in the late 1990s. Therefore, the use of previous key issues lists in
new surveys has limitations. |
| Fashion | The IS profession is notable for its fashion swings. In the last few years the hot
topics have included outsourcing, business process redesign and Internet. |
| Events | Certain events strongly influence ranking, for example the Year 2000 issue. |
| Overlaps | Some issues are not defined properly to avoid overlap with other issue(s). |
| Granularity | While some issues refer to broad general problems, other issues refer to more
narrow and specific concerns. |
| Theory | Application of theory is lacking in key issues selection. |
| Clarity | Some issues are not formulated and communicated properly to understand the
contents of the issues. |
| Causality | Some issues might, although ranked as unimportant, represent important driv-
ers of other key issues. For example, recruiting and developing IS human
resources might be an important driver of building an IT architecture. |
In this research, the selection of key issues will follow a three step procedure. Firstly, the US SIM issues (Brancheau et al. 1996) will be mapped to dimensions and categories as illustrated in table 6. The table can be used to identify both potentially missing issues and potentially overlapping issues. For example, there are no business relationship issues involving technology while there are four business relationship issues involving management-control-external. Then, the SIM issues will be generalised using the dimensions and categories. Finally, issues will be added and modified to minimise the effects of problems listed in table 5.

Note: In table 1, the top ten key issues from the US SIM study were listed. In this table, the top twenty key issues from the same study are listed. Dimensions and categories are the same as in Brancheau et al. (1996, Appendix D). The numbers in the columns are the ranks of the key issues. This table can be used to identify both potentially missing issues and potentially overlapping issues. A total of 32 different issues are possible in this matrix by combining four categories with three double dimensions. Several potentially missing issues can be identified. For example, there are no business relationship issues involving technology. Several potentially overlapping issues can be identified. For example, there are four business relationship issues involving technology.
issues involving management-control-external.

Key Issues Surveys
The dominating survey approach of key issues in IS management studies is the Delphi method. The Delphi method uses a series of questionnaires:

Essentially, the Delphi method employs a series of linked questionnaires. Successive rounds of questionnaires summarize subjects’ responses to the preceding questionnaire and ask respondents to re-evaluate their opinions based upon the summarized results. Questionnaire rounds are continued until a reasonable level of consensus is achieved. (Brancheau et al. 1996, p. 226)

The Delphi technique represents a methodology for organising and prioritising the collective judgement of a group through iterative surveying of the same group. The initial procedure is to prepare, distribute, and synthesize a series of issues for evaluation. Participants receive feedback in the form of their own previous responses and data describing the entire group. This enables participants to reaffirm original opinions, modify some and add new issues to the list. It is believed that the technique leads to consensus (Dekleva and Zupancic, 1996). However, the Delphi survey approach is associated with problems (Morgado et al. 1998) as listed in table 7.

Morgado et al. (1998) suggest extending the analysis of key issues in information systems management by demonstrating two techniques that may provide greater insight into the concerns of IS managers than the traditional rating method used by most recent key issues studies. Their research used Q-sort (Brown, 1980, 1993) and interpretive structural modeling (ISM) (Warfield 1994) based on a survey of banks in Brazil:

These approaches allowed us and the participating IT managers to gain a deeper understanding of the relationships among the key issues. A factor analysis on the Q-sort data identified three groups of banks with similar IT situations and strategies, and led to the conclusion that key issues can vary considerably among respondents. Application of ISM resulted in a revision of IT managers’ perceived priorities and proved to be a significant contribution to their understanding of their key concerns. (Morgado et al. 1998, p. 3)

The use of Q-sort to rank the key issues, followed by a factor analysis to identify three types of IS units in Brazilian banks, provided for more detailed dissection of key issues. The analysis highlighted that the consensus reported by the traditional key issues approach is somewhat illusory. The use of ISM provided a deeper understanding of the relationships among the key issues as shown in figure 1 based on Morgado et al. (1998). ISM forces IS managers and researchers to move beyond the independent consideration of key issues to evaluation of how issues interact.
Methodological Choices
In this research, the survey approach will follow a three step procedure as suggested by Morgado et al. (1998):

- **Questionnaire preparation:** The set of key issues selected on a theoretical basis as discussed in the key issues selection section of this paper, will be submitted in a series of meetings to IT managers in Norway. This group will add issues and require revision of the explanations for some other issues in order to adapt them to the local Norwegian conditions. Furthermore, complete instructions for using Q-sort for this list of key issues will be added and tested.

- **The survey:** The Q-sort material will be sent to IT managers in Norway based on the corporate membership list of the Norwegian Computing Society (Gottschalk 1998). The results of the Q-sort will be factor analysed to identify homogeneous groups of respondents and patterns of management concern or focus.

- **ISM workshop:** A group of IT managers, who participated in the survey, will be invited to a meeting to discuss the results of the survey and to participate in a session to review and structure the top ten key issues of the survey.

The distinguishing feature of Q-sort, a ranking technique, is that respondents are required to sort the supplied statements so that they fall into a predefined,
usually quasi-normal, distribution (Morgado et al. 1995). In this research, respondents may be asked to sort 25 key issues into nine piles as illustrated in figure 2. Only one issue can be placed in the most important (4) and most unimportant (-4) positions, while five issues can be placed in the middle position.

Conclusions
To provide greater insight into key issues in IS management in Norway, this research will select key issues on a theoretical basis and then conduct a multimethod study including Q-sort and ISM. However, this research is at an early stage making the paper serve primarily as a basis for discussion and feedback valuable for future research: What theories should be used to derive a set of key issues? Is the Niederman et al. (1991) classification appropriate? How serious are the major concerns with the current Delphi survey methodology? The empirical study of key issues in Norway is planned for 1999.

Note
1 A Web-site (http://www.cba.uga.edu/iris/) has been established to report details of each key issues study.
