A Comparison of the Most Important Website Features in Different Domains:
An Empirical Study of User Perceptions

Abstract

This study uses an inductive thematic analysis approach to examine user perceptions on the importance of website design features in six different website domains: Financial, E-Commerce, Entertainment, Education, Government, and Medical. The five most important features, as well as the five most important families of features, were identified for each of the domains. The results indicate that (1) there are certain features that are equally important among different domains; (2) there are other features that are extremely important for one domain and extremely unimportant for another. The study provides empirical evidence for website designers and evaluators about which features are more important to focus on when dealing with different domains of websites. It adds value to the current literature on consumer behavior in the electronic environment and web usability studies.

Introduction

In the web environment, users are consumers. Understanding consumers' expectations and how they feel about the websites they use has recently become more important. Few current web usability studies are based on either theoretical frameworks or empirical evidence (Conger & Mason 98; Small 98; Spool et al. 99; Wilkinson et al. 97). Most studies provide some guidance for designers largely based on heuristics or rules of thumbs. These studies do not identify website design features that contribute to consumer satisfaction or dissatisfaction, address different quality expectations, nor do they provide any insight into whether some features are perceived more important than others by the users.

Zhang et al. (1999, 2000) provided an emerging theoretical framework to distinguish between the website design features that satisfy users from those features that dissatisfy users. In their study, subjects were asked to classify certain features into satisfiers and dissatisfiers, which showed support for the framework. Von Dran et al. (1999, 2000) approached the issue from a different angle. They applied a marketing model to the web environment by focusing on users' different quality expectations.

Again, the empirical data showed that the model can be used to distinguish the features that meet users' basic, performance, and excitement quality needs.

Both studies imply that the specific web domain or the purpose of a website impacts what users think about the features as satisfiers/dissatisfiers or how they meet different quality needs. On the other hand, the studies did not address user perceptions on whether some features are relatively more important than others.

The objective of this study is to use a bottom up approach to examine user perceptions on the relative importance of features in different domains. The results show that (1) the importance of features or families of features is dependent on the particular domain a user is working with; (2) certain features or families of features are extremely important for one domain and extremely unimportant for others; (3) there are certain features or families of features that are equally important among all domains. The current study provides designers with empirical data of the most important features to focus on when faced with design capacity limitations.

Research Method

Few existing studies provide either theoretical frameworks or heuristics of examining the relative importance among website design features. Thus, there are few existing theories or models that can be used to guide the study. We decided to use an inductive (data driven) thematic analysis approach (Boyatzis, 1998) in this study.

Data Collection

Six domains of websites were chosen for the study. They were:

- Financial Information Websites (such as CNNfn.com, quote.yahoo.com)
- E-Commerce Websites (such as Amazon.com, e-Bay.com)
- Entertainment Websites (such as a cartoon or a game website)
• Educational Websites (such as National Geographic or a university's website)
• Governmental Websites (such as US Department of Labor, and the White House website), and
• Health or Medical Information Websites.

In a survey, subjects were asked to list, in priority order, the five most important website features for each of six different website domains. 67 graduate students at a major northeast university participated in the study. Among the subjects, 32% were male and 68% female. The average age was 33 (with a standard deviation of 8). Subjects were paid $10 upon their completion of the survey. Three of the subjects did not understand the requirement and provided unusable answers, and these sets of data were dropped during the analysis. Table 1 shows example answers from one subject.

Coding in Thematic Analysis

Thematic analysis (Boyatzis, 1998) was conducted on the subjects' answers to the questions. In this data-driven approach, two independent raters worked directly from the raw answers to extract words and phrases, which were used to generate the codes. This close relation between the codes and the raw answers helped to improve the coding consistency between the raters. The codes are measured by the magnitude of the appearance (that is, frequency). The software used for the coding was ATLAS.ti, version WIN 4.2.

Developing an initial code schema

The unit of the analysis (defined as a quotation in ATLAS.ti) was regarded as the whole answer a subject had for one domain. The unit of coding (a code in ATLAS.ti) was the particular features that subjects listed in their answers. The codes were developed using the original words and phrases in the quotations in one domain, the financial domain. Most responses in the survey are manifest, however, some are latent, which required interpretation by the raters (Boyatzis 98, p16). A consensus meeting with a third rater resolved the disagreements between the two independent raters. This included establishing rules of how to break quotations into meaningful units of coding while keeping the priority ranking provided by the users in the codes. Thus, for s181's answer for the entertainment domain (which is a quotation, see Table 1), five codes were developed with the priority embedded in the codes: (1) multimedia, (2) interaction, (3) display/images/graphics, (4) quick download time, and (5) links.

In this paper, a super code is defined as a term with distinctive meaning; and a code is a super code with a suffix indicating the priority. For example, "customization" is a super code and may include five codes: customization 1, customization 2, customization 3, customization 4, and customization 5. It is thus possible that in a particular domain, only one or two codes were used from a super code.

Scaling of the initial code schema

Before the code schema was applied to other domains, the super codes were scaled (Boyatzis 1998, p134) into a more manageable list. This included the consolidation of similar super codes as a new super code with a higher level of abstraction. For example, after the scaling, the codes for s181's quotation for the entertainment domain became (1) multimedia 1, (2) interaction 2, (3) visual design 3, (4) site responsiveness 4, and (5) links to information 5. The result of the scaling was a new code schema of 118 codes.

Application of the code schema to other domains

When the two raters coded the remaining domains, the original words or phrases from the subjects were either identified as belonging to an existing super code or a new super code. Consensus meetings were conducted for coding results of each of the domains and the inter-rater reliability scores were calculated both before and after the meetings. All inter-rater reliability scores are above 85%.

Clustering similar codes into families

Clustering is defined as “...the organization of multiple themes into groups” (Boyatzis, 1998, p134). The clustering of the super codes revolved around the creation of families and placement of super codes within those families. For example, the family of “Navigation” included codes like “easy to navigate,” “navigation aids,” and “clear layout of information,” to name a few. The clustering was based on the code schema and not on any previous theories, so these families more accurately reflect the respondent’s answers.

Overall scaling and clustering

As an iterative process, scaling was conducted again once all domains were coded. This scaling task is coupled with the refinement of families. Several super codes with single responses (one response for the entire super code) were compressed with other super codes. Similarly, family memberships were adjusted in order to eliminate families with only one super code and to reflect stronger semantic coupling among super codes.

Data Analysis and Results

Some subjects mentioned that they did not use or never used websites in certain domains (see s181 in e-commerce domain in Table 1). Thus, they could not and did not provide any opinions on which features were most important. For those participants who provided their perceptions on some or all domains, the analysis was conducted at two levels: the code and the cluster (or family as noted in ATLAS.ti) of codes. Sometimes designers or evaluators of websites need to focus on a
small number of factors that affect user perceptions of websites. Thus, it may be helpful to group features into a higher level of abstract units, namely clusters or families of features. These families may provide a better overview of the characteristics of website features. Since subjects were able to give a list of features with priority (order of importance), we used this information in our analysis in the form of weighted frequencies at both the code and family levels.

Weighted Rank of the Most Important Features for Different Domains

For each code in each domain, the weighted score is determined by the frequency of the code in the domain multiplied by the weight for the priority that was assigned by the subjects. That is:

\[
\text{Score} = \text{PriorityWeight} \times \text{Frequency},
\]

while PriorityWeight is defined as: First priority (most important) has a weight of 5, Second (second most important) 4, third 3, fourth 2, and fifth 1.

Table 2 lists the five most important features for each of the six domains based on the weighted frequencies. The following are some observations from the table.

1. The Financial domain has high requirements on the nature of the information, such as up to date, accuracy, multiple sources, and timeliness.
2. Easy to navigate is also very important as ranked as number 4 for the financial domain. For all other domains, however, easy to navigate is highly ranked as either number one or two. Thus, it is a must-have feature for all six domains.
3. Up-to-date information is very important for the financial domain, and is true for the government, medical and entertainment domains. The feature, however, is not listed within the five most important features for the education and e-commerce domains.
4. The Entertainment domain has high demand on visual design, multimedia and site responsiveness, which are not in the list of any of the other five domains.
5. Search tool is commonly ranked by the following four domains as important: education, government, medical, and e-commerce.
6. The Education and medical domains require comprehensiveness of information, which is not ranked within the five-most important list in the other four domains.
7. Accuracy of information is most important for the medical domain, somewhat important for the financial, education and government domains, but is not within the five-most for the e-commerce and the entertainment domains.
8. Security of data is ranked number one in e-commerce domain but does not appear in any other domains.

Weighted Rank of the Five Most Important Families for Each Domain

There is a total of 15 families/clusters of features as shown in Table 3. One of them is for the responses of "Do not use / never used the domain" and is disregarded from the analysis. The weighted score of a family is calculated by using the weighed scores of the super codes belonging to the family. Table 4 lists the five most important families for each of the six domains. Table 4 shows that:

1. Navigation is ranked among the top three most important families in all domains.
2. Completeness/Comprehensiveness of Information is among the top two most important families in all but the E-commerce and Entertainment domains.
3. Site Technical Features (most responses are from Search Tool feature) is ranked from the 3rd to the 5th family in all but Financial and Entertainment. This implies that users take whatever is available on the first page (immediate access)of these domains. They don't expect to search in these websites.
4. Currency/Timeliness/Update is among the top three for the Financial, Medical and Government domains.
5. Accuracy is listed as the 4th or 5th family for the Financial, Medical and Government domains.
6. Readability/Comprehension/Clarity is ranked as 4th or 5th for the Financial, Education, and E-Commerce domains.

Table 4 also indicates there are three domains that require unique families. For example, the Education domain requires Information Reliability/Reputation; E-Commerce demands Security/Privacy and Product and Service Concerns; while Entertainment requires four unique families: Visual Design, Engaging, Information Representation, and Site Accessibility/Responsiveness.

Figure 1 depicts the similarities or differences among the domains in terms of the composition of the most important families. Some domains share the common families. Figure 1 confirms some of the observations from Table 4. Specifically, Figure 1 shows that:

1. The Government, Education and Medical domains have similar "patterns" of the most important families. For example, they all have high F02 and F07 and low F04, F06, F09, F12, and F13. This means that designers can focus on the concerns that these domains have in common.
2. The Financial, E-Commerce and Entertainment do not seem similar to any other domains, or to each other. This implies that these domains should be designed differently from other domains focusing primarily on the particular reason that users come to the sites.
For the E-Commerce domain, users treat products/services as website features. This implies that having impressive or great website features alone is not enough—users need good products and services from the website.

Discussion and Conclusions

The analyses of codes and the families of codes show some interesting facts about users' perceptions on importance of website features and families of features.

1. The importance of features or families of features is dependent on the particular domain a user is working with.

2. Certain features or families of features are extremely important for one domain and extremely unimportant for others. For example, Engaging is the 2nd most important for Entertainment, but almost the least important for the other five domains; Security/Privacy is the most important family for E-Commerce domain but is not listed as important in the rest of the domains.

3. There are certain features or families of features that are equally important among different domains. For example, Navigation is among the top of important families in all the domains.

The findings provide practical suggestions to at least three types of people. For website designers, the study implies that different domains should be designed with different foci of important features. For website owners or corporate strategists of E-C websites, the study indicates that users regard the website design and company products/services as one unit. For independent website evaluators/critics, this study recommends that different domains require different sets of evaluating criteria/tools.
